

Formation of High Eccentricity GW Mergers

Johan Samsing
Princeton

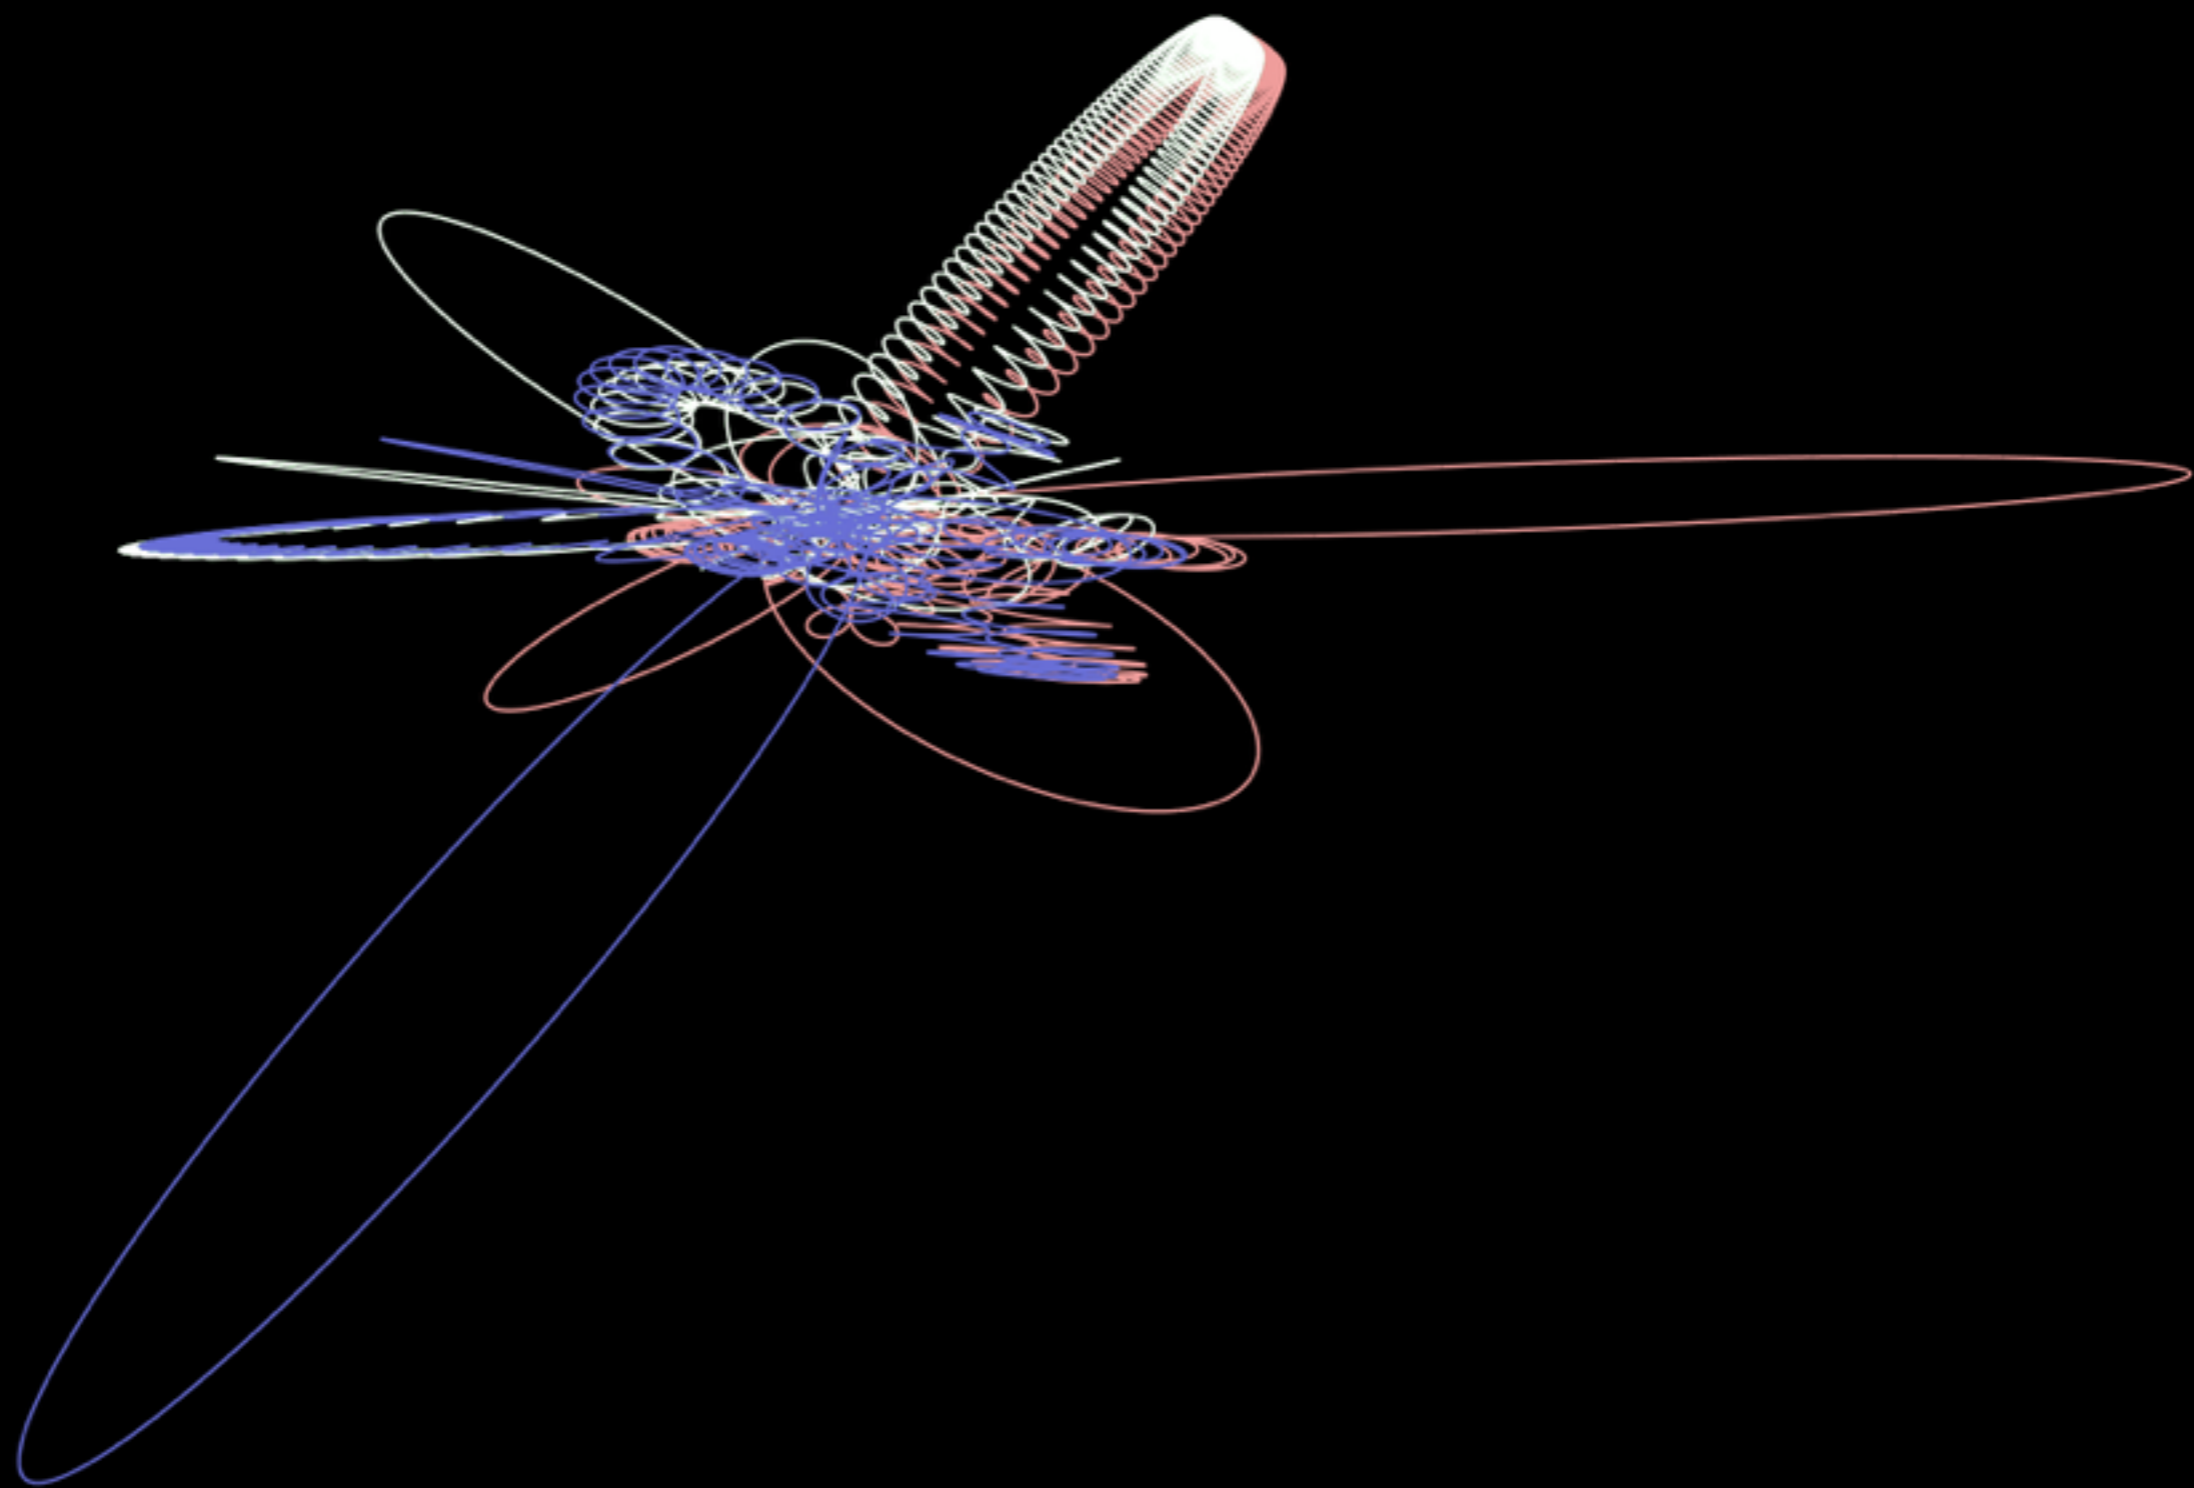

What is the origin of BBH mergers?

- * Spin
- * Mass
- * Eccentricity

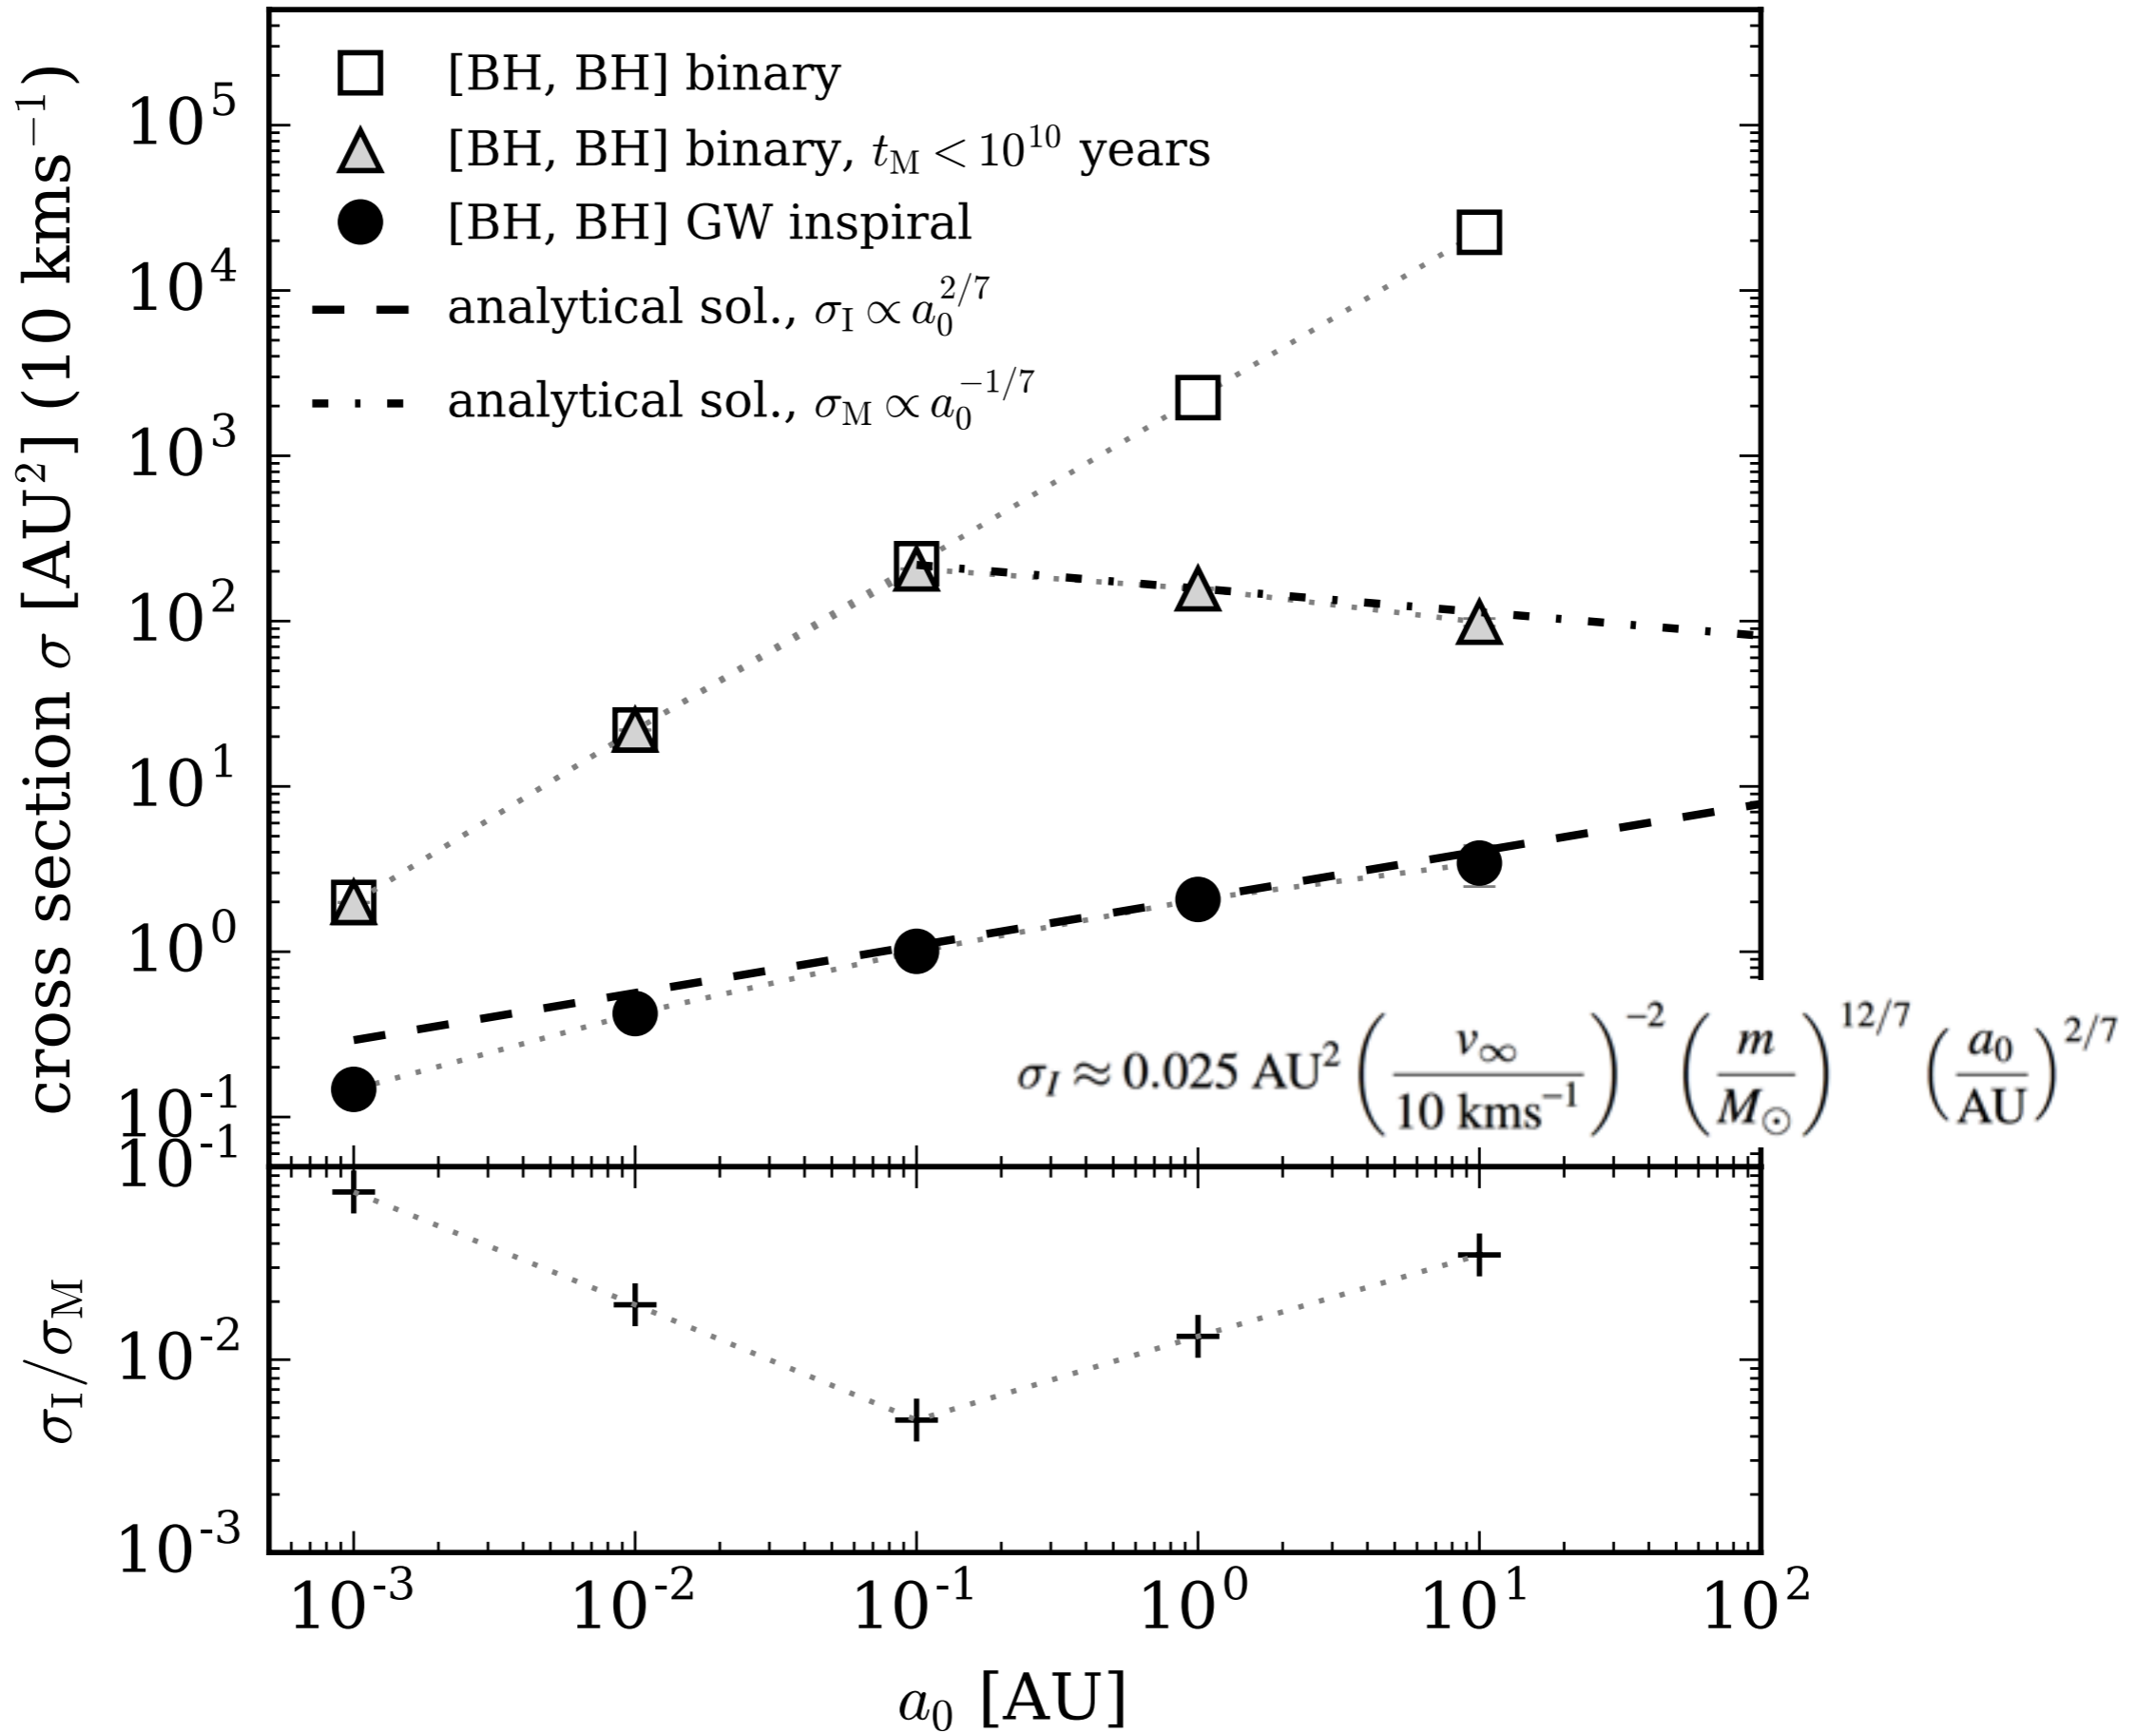

BH-BH GW Inspiral

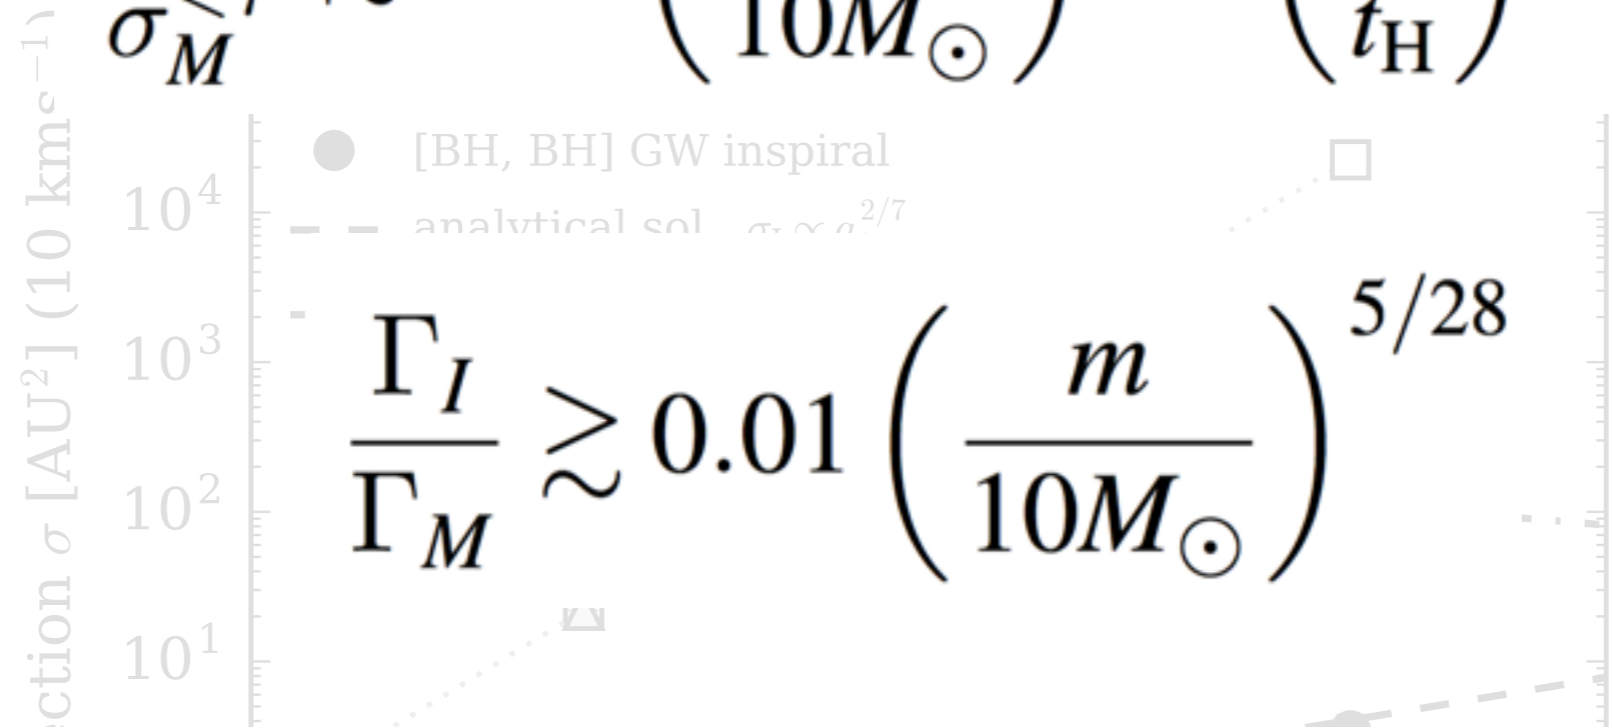

GW Mergers and Inspirals

Analytical Solution

$$\frac{\sigma_I}{\sigma_M^{<\tau}} \gtrsim 0.01 \left(\frac{m}{10M_\odot} \right)^{5/28} \left(\frac{\tau}{t_H} \right)^{-5/28}$$

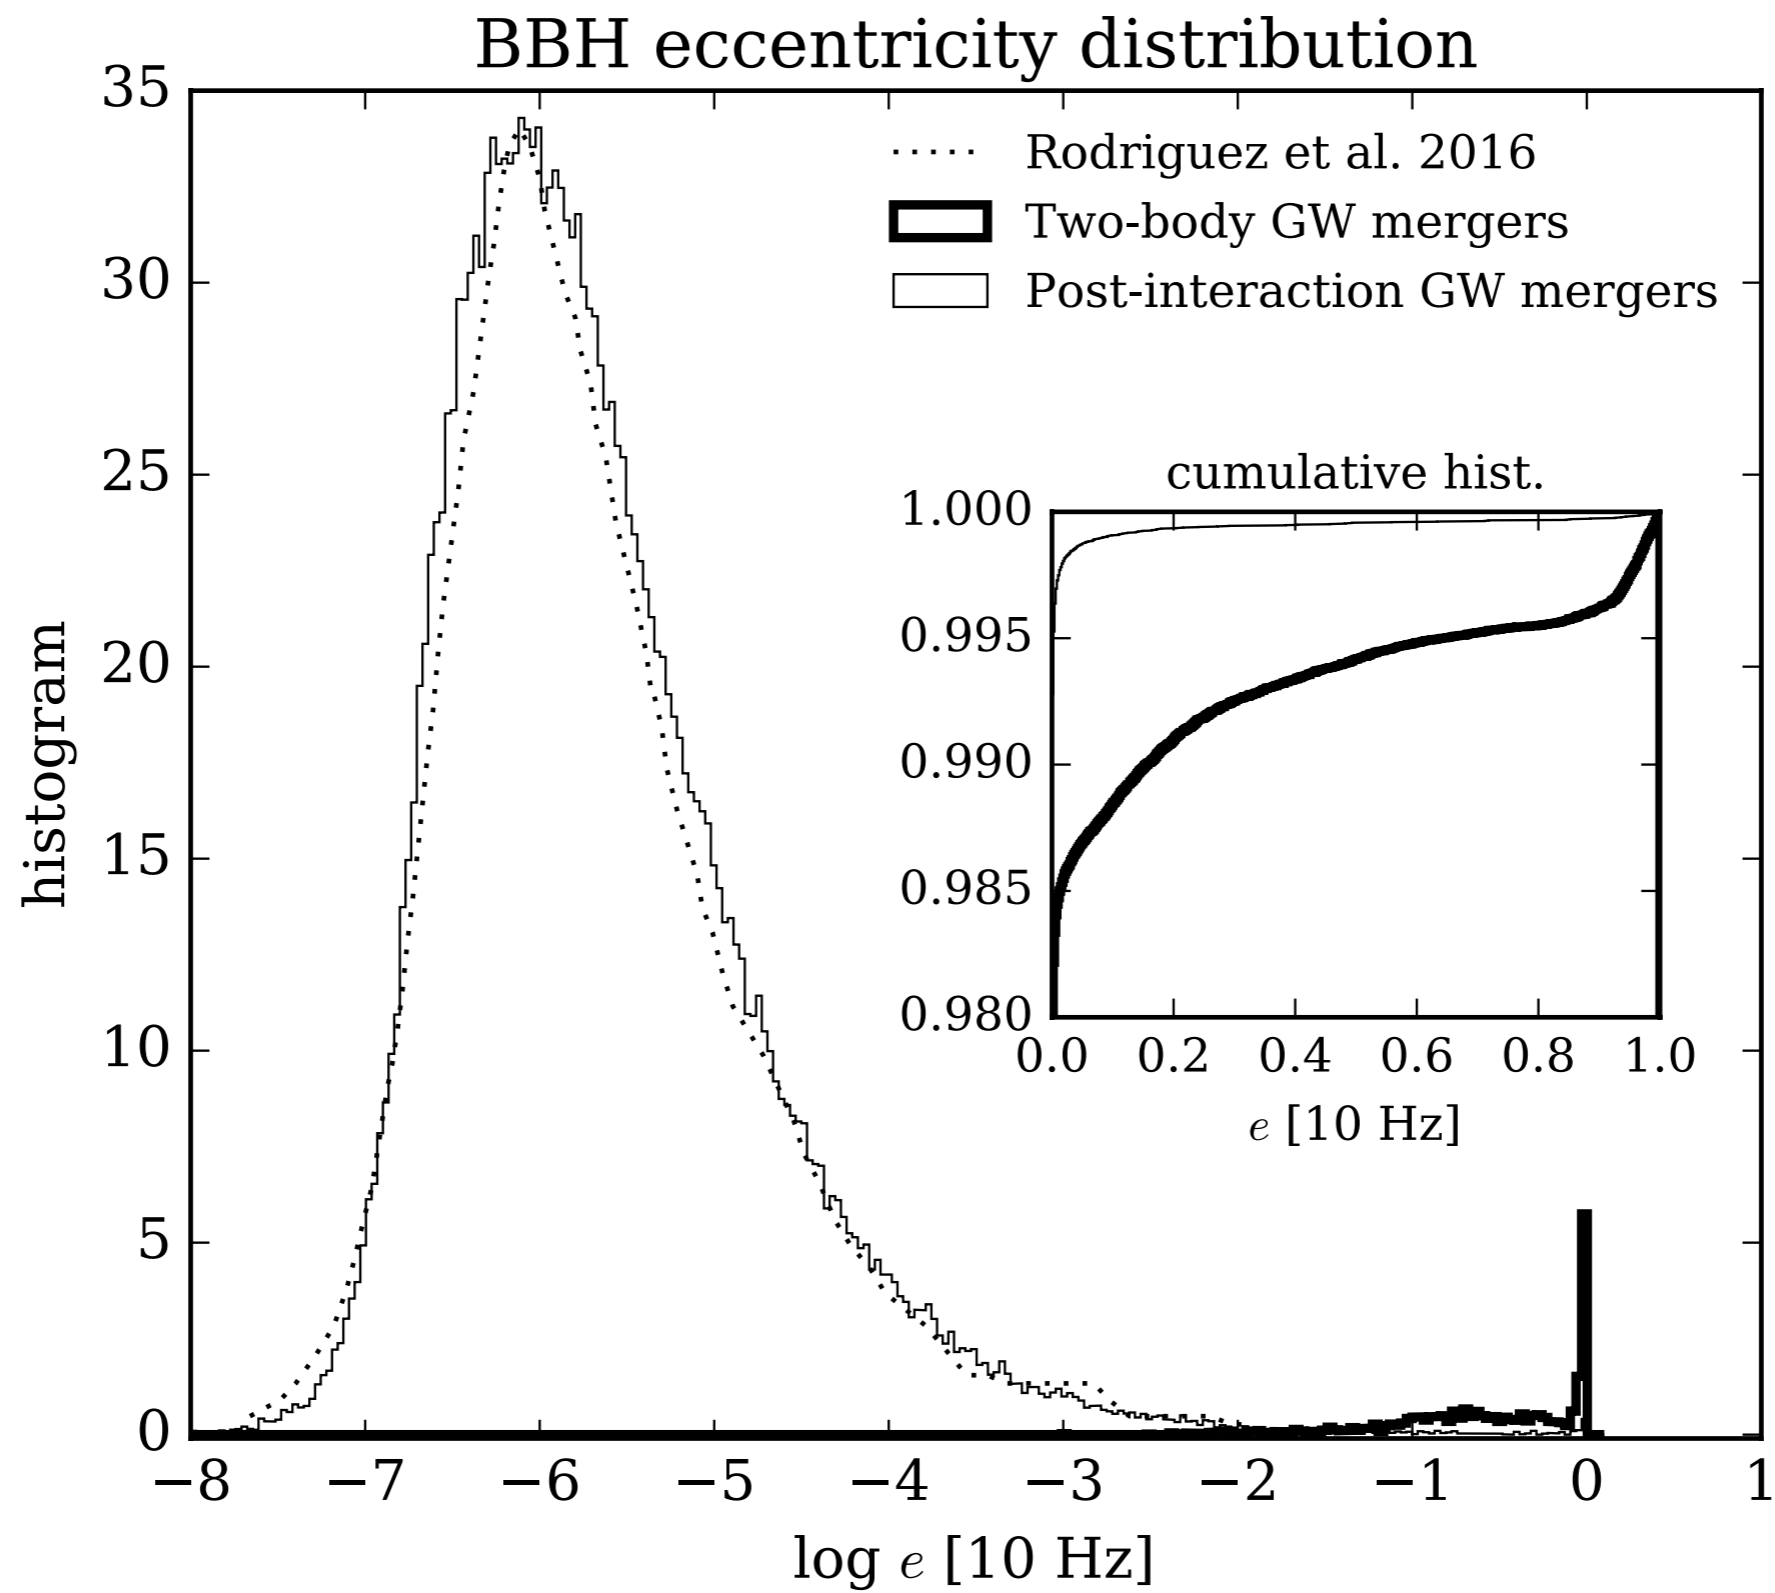

$$\frac{\Gamma_I}{\Gamma_M} \gtrsim 0.01 \left(\frac{m}{10M_\odot} \right)^{5/28}$$

$$\frac{\Gamma_{f_{\text{GW}}}}{\Gamma_I} \approx 0.2 \left(\frac{m}{20M_\odot} \right)^{-8/21} \left(\frac{f_{\text{GW}}}{10\text{Hz}} \right)^{-2/3} \left(\frac{a_0}{0.1\text{AU}} \right)^{-2/7}$$

No 'N-body groups' incl. these corrections yet.

Current work.

- * Improve analytical models (higher fractions?)
- * Analyze full globular cluster simulations.
- * Eccentricity distribution: compare different models.

Not all interactions are equally likely

Colorful Black Holes

John Hawking (artist)
Department of Astrophysical Sciences

Each panel in the picture shows the result of a gravitational interaction between a binary and a single black hole, where the binary is seen in the initial binary phase and the single hole is the merged remnant. The three black holes often undergo a chaotic dance before an inevitable collision. Often the dance is set for at least two of the black holes, as the red and black colors indicate various tidal collisions. The remaining colors indicate different ways for the black holes to interact. By tracking the black and red growth, we can show that more than one period of all-black-hole collisions forming in dense stellar systems throughout the universe will have a rich special gravitational wave signal that can be observed here on Earth. The picture also shows that the chaotic three-body problem is not as chaotic as one might think.

THANK YOU
