

AHELP for CIAO 3.4

eval

Context: [slangrtl](#)

Jump to: [Description](#) [Example](#) [See Also](#)

Synopsis

Interpret a string as S–Lang code

Syntax

```
eval (String_Type expression, [,String_Type namespace])
```

Description

The eval function parses a string as S–Lang code and executes the result. If called with the optional namespace argument, then the string will be evaluated in the specified namespace.

This is a useful function in many contexts such as dynamically generating function definitions where there is no way to generate them otherwise.

Example

```
if (0 == is_defined ("my_function"))
  eval ("define my_function () { message (\\"my_function\"); }");
```
